

① constant T effects

$$ATT_k(t) = ATT_k \forall t = ATT$$

Staggered T DD

① constant T effects

if // trends $VWCT=0$

Δ and $\Delta ATT=0$

so $\beta_{TWFE} = VWATT$
variance-weighted avg of ATT_k s
(constant over t)

② dynamic T effects identical across units (Meer and West 2013)

$$\frac{(6-4) - (8-5)}{VWATT \quad \Delta ATT}$$

even if $VWCT=0 \rightarrow \Delta ATT \neq 0$

this bias only present ~~here~~ in a single-coefficient specification, not in event study, but see Borusyak and Jaravel (2017) for other issues with event study if no never-treated group

③ dynamic T effects differ across units

again $\Delta ATT \neq 0$ always and since T effects don't evolve the same way across units, so even if "line up" event time, the Δ s over time diff for k as for l and will bias results

if bias bad enough switch to other method like stacked DD (Dehpande and Li (2017)) or Callaway and Sant'Anna (2021)
